This application note describes implementing a USB Audio Device on the FT900. The Wolfson/Cirrus WM8731 Digital to Audio Convertor on the MM900EVx modules are used to convert an audio data stream from a host PC to an analog output.

Use of Bridgetek devices in life support and/or safety applications is entirely at the user’s risk, and the user agrees to defend, indemnify and hold Bridgetek harmless from any and all damages, claims, suits or expense resulting from such use.

1 Introduction

The FT900/FT901 and FT905/FT906 devices include an I²S interface which is typically used to stream digital audio data to a Digital to Audio Convertor. This application note describes how to bridge this interface to a host PC.

1.1 Overview

The FT90x contains both an I²S interface and I²C interface. These can be used to stream digital audio data to a DAC. The audio stream is sent via I²S and the DAC is normally controlled via I²C.

The USB device interface may be configured to report a USB Audio Device and receive a suitable audio stream from a host PC. This can be received by the FT900 and subsequently streamed to the DAC.

There is a large choice of suitable DACs available. The MM900EV2A module has a Wolfson/Cirrus WM8731 device on-board which is connected to the I²S and I²C busses. The main target for this application note is the WM8731 although sections of code which are specific to this device are clearly identifiable.

Third-party open source code is used to implement a TCP/IP stack in this application note:

- Printf – tinyprintf.

Links to resources for these libraries are in Appendix A – References.

1.2 Scope

The firmware application for the USB Audio Device assumes a fixed audio resolution and sample rate. There is no mechanism for the host PC or user to change the audio streaming properties dynamically.

There is no hardware volume or mute control. Host operating systems must be able to manage the output by manipulating the data in the output stream.

1.2.1 Features

The application note highlights the use of I²S to stream audio data and I²C for controlling a DAC. Simple buffering is demonstrated but an unbuffered option is shown to provide a low latency data path from USB to the DAC.

1.2.2 Enhancement

Enhancements to this application might include:

- Add support for 24 bit audio and 96 kHz sampling.
- Allow multiple interfaces to be selected by the host PC to change the audio resolution or sampling rate.
- Reduce the overall size of the application code.

This USB Audio Device example application should be treated as an example. Full source code is provided allowing users to build and modify if required:

http://brtchip.com/wp-content/uploads/FT90x/AN_433_FT90x_USB<Audio Device_V1.1.zip

See section 6 Importing into the FT9xx Toolchain for more information on modifying the project using Eclipse.
2 Project Overview

The project files for the application are divided into the following folders.

<table>
<thead>
<tr>
<th>Folder</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source</td>
<td>Application source code and abstraction files.</td>
</tr>
<tr>
<td>lib</td>
<td>Library files.</td>
</tr>
<tr>
<td>lib\tinyprintf</td>
<td>tinyprintf library.</td>
</tr>
</tbody>
</table>

Table 2.1 Project Files Overview

The application source code is contained within the "Sources" folder.

In the code, the main() function and the high-level functions of the application are in the "main.c" file.

2.1 Main Program

The server main program is responsible for detecting a connection from the FT900 to the host PC and instantiating a USB Audio Class Device when enumerated by the host. It will also initialise the WM8731 DAC to receive an audio stream in the format which the USB descriptor requested from the host PC.

2.2 I^2S Code

When buffering is enabled the I^2S on the FT900 is used as an interrupt driven interface. There are interrupts when the on-chip buffer is half empty and fully empty. The algorithm used in this application receives and buffers packets of data from the USB interface and writes then in a larger transfer to the DAC. A circular buffer is used for the grouping of data.

If buffering is disabled then data received from the USB interface is written directly to the I^2S interface. The interrupt service routine for the I^2S is used to pad any missing data with zero data.

2.3 USB Interface

A handler has been implemented for USB Audio Device class requests. Only class requests used by the Windows USB audio device driver are implemented.

Configuration descriptors are provided for hi-speed and full-speed operation. USB Audio Device configuration descriptors are included. These describe the capabilities and audio formats used by the USB Audio Device and supported by the DAC.

2.4 Power Management Handler

When moving between suspend and resume states on USB, the power management handler is required to notify the USBD (USB device) library that the bus state has changed.
2.5 Other Features

The DFU-C facility can be enabled for this application. This is called from the macro
STARTUP_DFU() in the main() function. It will briefly enable the USB device on the FT90x and
allow a DFU utility to update the application code. This can be removed entirely or configured to
alter the number of milliseconds it will wait before closing the USB device and continuing with the
application.
3 Code Structure

When buffering is enabled: After initialization data received from the USB is buffered by the main task code which updates a circular buffer. The I^2S interrupt level code takes data from the circular buffer and sends it to the I^2S interface where it is converted into analog audio.

The streaming data from the host arrives in a frame pattern, which for stereo 16 bit 44100 Hz samples is either 176 bytes or 180 bytes; and for stereo 16 bit 48000 Hz is 196 bytes. This is grouped into a larger packet of 512 bytes to be transmitted to the DAC. A small latency of around 3 ms is therefore gained. There is, however, a 1 kB buffer in the I^2S interface which needs to be fed data to ensure that there are no gaps in the stream. The re-fill is triggered at the half full point of the buffer which allows the I^2S interrupt routine time to send additional data to the back of the buffer while the data at the front is being consumed. At higher data rates the latency will reduce.

If buffering is not enabled: Data received from the USB interface is directly written into the I^2S buffer. If the I^2S buffer is depleted then the I^2S interrupt level code adds a small amount of data to the buffer to prevent the I^2S bus from stopping due to lack of data.

The FT90x API is used to manage the USB interface and to send data via the I^2S interface to the DAC. Various other calls are used to supporting interrupts and a UART monitor/debugging interface.

More information on these FT90x API functions can be found in AN_365 FT9xx API Programmers Manual.
4 USB Configuration

4.1 High-speed Configuration Descriptor

The following configuration descriptor is taken from the FT90x device by "USBView" from Microsoft. It is based on the configuration where:

- The DAC is a WM8731.
- The audio resolution is 16 bit.
- The data format is uncompressed PCM.
- The sample rate is 48000 Hz.

Device Power State: PowerDeviceD0

4.2 Full-speed Configuration

The full-speed Configuration Descriptor is identical to the high-speed descriptor.
5 Testing

This section describes how to test the audio device on Windows. Two options are available:

- An MM900EV2A module with a headphone jack.

![Figure 5.1 MM900EV2A Module](image)

- An MM900EV2A module with speakers connected. JP2 must be set to the ON position and speaker connected to CN10 and CN11 for left and right channels respectively.

Each module was connected to and powered by a PC running Windows 7 or Windows 10.

To program the example code onto the FT900 device on the MM900EV2A board, refer to the application note AN_325_FT9xx_Toolchain_Installation_Guide. The binary file name is "AN_433_FT90x_USB_Audio_Device.bin" and it is found in the "Debug" directory.

5.1 Playback

Once the USB Audio Device has been enumerated by Windows it will then install a device driver automatically. The application is designed to be identical to a standard audio device and use the standard audio device drivers from Windows.

After the device drivers have been installed then the Windows system controls can be used to select the device as the default audio device.
6 Importing into the FT9xx Toolchain

The AN_433 Firmware found at the following link can be easily imported into the FT9xx Toolchain:

http://brtchip.com/wp-content/uploads/FT90x/AN_433_FT90x_USB_Audio_Device_V1.1.zip

Once installed, select File --> Import --> General --> Existing Projects into Eclipse, and point to the downloaded and extracted project directory.

The project will appear in Eclipse Project Explorer as shown in Figure 6.1.

![Figure 6.1 Eclipse Project Structure](image)

6.1 Changing the Application Software

The application software provided can be altered and changed if required. The FT9xx Toolchain is a free tool to enable code development and debug for the FT90x series and is based on plug-ins for the free popular IDE using the GCC compiler.

With each software change, the project should be rebuilt and reprogrammed into the FT90x IC. Please refer to AN_325 FT9xx Toolchain Installation Guide for further information.
